

I'm not robot

**Continue**

Bridging Mode Radius configuration Country Code NTP configuration, and so forth. The WLCs will reboot after you save the configuration at the end. Keep-alive packets are sent on the Redundancy Port to the Standby to the Active WLC every 100 msec (default timer) in order to check the health of the Active WLC. Issue the schedule-reset command as per planned outage with the no swap option in order to reset the APs and WLCs so that they can boot with the new image. In the case of power failure on the Active WLC or some crash where the direct command for switchover cannot be sent, it may take 350-500 msec depending on the number of APs in network. Both the WLCs in HA setup keep track of gateway reachability. Primary WLC connected to one 6500 and the Stand-by WLC to the other 6500. Initiate a force switchover again on current active WLC. In case of Box Failover i.e. Active controller crashes / system hang / manual reset / force switchover direct command is sent from Active controller via Redundant Port as well as from Redundant Management Interface to Standby controller to take over the network. If there is no acknowledgment of the third Keepalive packet within 50 msec, the Standby WLC immediately sends another ICMP message to the Active WLC via the redundant management interface. Currently during the HA pairing process, once the active-standby role is determined, the configuration is synced from the active WLC to the standby WLC via the Redundancy Port. It is important to make sure this VLAN is dedicated for the HA process and is not part of any Data VLAN, or else it may result in unpredictable results. The CLI should be used to configure one WLC as the Standby WLC (as mentioned in the configuration section) provided it satisfies the requirement of minimum permanent license count. On event of Active failure, HA SKU will let APs join with AP-count obtained and will start 90-day countdown. If required, the Standby WLC (WLC 2, in this example) can only be managed via the Console or Service Port. When the previous Active WLC comes back, it will not take the role of the Active WLC, but will negotiate its state with the current Active WLC and transition to a Standby state. The AP's CAPWAP State (only APs which are in a run state) is also synced, and a mirror copy of the AP database is maintained on the Standby WLC. From this point onwards GUI/Telnet/SSH for WLC 2 on management interface will not work, as all the configurations should be done from the Active controller. Because WLC in maintenance mode does not participate in HA process it need to be manually rebooted to bring it out of maintenance mode and make participate in HA process again. The time it takes for failover in case of power failure on an Active Box also depends on the Keepalive timer configured on the WLC (configured for 100 msec by default). If WLC cannot discover its peer within this time it will transition its state to maintenance mode. Once the Standby WLC receives the image from the Active WLC, it starts executing upgrade scripts. There are no specific requirements for this document. Once the HA pairing is formed, Cisco Prime removes/deletes the WLC 2 entry from its database as both the WLCs have the same management IP address. AP uptime as well as Association UP Time is maintained and AP did not go in discovery state. Also, clients continue their connection with the new active controller in a seamless manner. WiSM-2 WLCs have a dedicated Redundancy VLAN which is used to synchronize the configuration from the Active WLC to the Standby WLC. OEAP (600) clients are not supported. That is, Up Time and Association Up Time is maintained on both the WLC, and when switchover is initiated, the Standby WLC takes over the network. This will benefit due to the following factors: ICMP ping packets might get discarded under heavy loads. Also, peer-search timer and keep-alive timer are modified to support an extended range. The Redundancy Port is also used in order to check peer reachability sending UDP keep-alive messages every 100 msec (default timer) from the Standby WLC to the Active WLC. In the event of a switchover, the new Active WLC will operate with the license count of the previous Active WLC and start the 90-day countdown. In the next reboot after role determination, it validates the configuration again, reports no XML mismatch, and process further in order to establish itself as the Standby WLC. Also, once Peer WLC transitions to the STANDBY HOT state, the -Standby keyword is automatically appended to Standby WLCs prompt name. New mobility is not supported. WLC 2, which was initially added in Cisco Prime with an IP address 9.6.61.3, is deleted from Cisco Prime database after HA pairing is formed. When the HA pair is set up, by default, the Primary WLC's MAC address is synced as the Mobility MAC address on the Standby WLC which can be seen via the show redundancy summary command on both the controllers. WLC, which was configured as Primary Unit, should now be active and WLC, which was configured as Secondary Unit i.e., WLC 2 should be in Hot Standby State. To enable SSO navigate to Controller > Redundancy > Global Configuration and select the Enable option from SSO drop-down list on both the WLCs and click Apply. AP-count license info will be pushed from Active to Standby. In the HA setup, the AP's CAPWAP state is maintained on the Active WLC as well as the Standby WLC (only for APs which are in a Run state). PMIPv6, NBAR, SIP static CAC tree are not synced, need to be re-learned after SSO. With Client SSO, the client's information is synced to the Standby WLC when client associates or the client parameters change. In AP SSO deployment controller running higher permanent count licenses should be configured as primary unit. The controller's LSC certificate and SCEP configuration must be implemented on the active and standby controllers before activating SSO. Tagging of the RMI and management interfaces is now mandatory in release 8.0 to pair WLCs in SSO mode. If the WLCs cannot reach each other via Redundant Port or via the Redundant Management Interface, the WLC configured as Secondary may go in to Maintenance Mode. Both the interfaces should be in same subnet as Management Interface. Complete these steps: 1. For WLC 1: b. Client SSO will work with Anchor-Foreign mobility setup as well as Guest Anchor scenarios. It needs to be configured on WLC 2 where 9.6.61.23 is the Redundancy Management IP Address of WLC 2 and 9.6.61.21 is the Redundancy Management IP Address of WLC 1. Once SSO is enabled, it will reboot the WLCs. While it boots, the WLCs negotiate the HA role as per the configuration via Redundant Port. Will go into maintenance mode if still not reachable. The secondary controller will get upgraded just like it does when upgrading the regular code. With no acknowledgment of three keep-alive packets from active WLC, standby declares active as dead and takes over the network. After pre-image is completed on all the APs, issue the show AP image all command in order to verify that the primary image on the WLC is set as the backup image on APs. 8. It will not disconnect connected APs. With new the WLC coming up, HA SKU at the time of paring will get the AP Count: ~ If the new WLC has a higher AP count than the previous, the 90-day counter is reset. debug redundancy config-sync errors/events/detail 6. ~ In order to lower AP count after switchover, the WLC offset timer will continue and nagging messages will be displayed after time expiry. Once selected, click the Configuration tab, which provides all the options needed to configure the WLC 1, and repeat the steps for WLC 2. Down No Yes Yes Yes Switchover happens and this may result in Network Conflict Down No Yes No No Standby will reboot and check for gateway reachability. Mismatch may result in Maintenance Mode. debug redundancy transport detail/errors/events/packet 3. Config-Sync Figure 13 Redundancy Statistics GUI The Infra statistics contain RF Client details and Sanity Counters as shown in Figure 14. Associate an AP to the WLC and check the status of the AP on both the WLCs. In the HA setup, a mirror copy of the AP database is maintained on both the WLCs. That is, APs CAPWAP state in maintained on Active as well as Standby WLC (only for APs which are in Run state) and when switchover is initiated, the Standby WLC takes over the network. debug redundancy mobility events/errors/detail 9. show redundancy infra statistics 10. Check the WLAN summary and Interface summary on standby WLC from console connection. WLC 1: WLC 2: 7. 7. Now configure one controller as Primary and another controller as Secondary from Redundant Unit drop-down. In other words, no layer 3 interface should be created for this VLAN and can be allowed on VSL Link to extend HA setup between multiple chassis in VSS setup. If the WLCs cannot reach each other via the Redundant Port or via the Redundant Management Interface, the WLC configured as secondary may go in to Maintenance Mode. AP-count license information will be pushed from Active to Standby. On the Standby controller, serviceability debugs related to the gateway reachability of the active controller and standby controller, their health states, and actions taken based on this information is reported. Bulk configuration during boot up and incremental configuration are synced from the Active WLC to the Standby WLC using the Redundant Port. This mechanism is applicable only to the standby WLC. After the WLCs are configured in the HA setup, the Standby WLC cannot be upgraded directly from the TFTP/FTP server. It is recommended that you use DHCP address assignment for the service port in the HA setup. Configure one WLC as Primary and the other WLC as Secondary from the Redundant Unit drop-down list. After the WLCs are configured with Redundancy Management and Peer Redundancy Management IP Address, and the Redundant Units are configured, it is time to enable SSO. This can be done using the configure redundancy mobilitymac command on the Active WLC. If they are not in order, you must change the port channel distribution to be fixed and reset Cisco WiSM2 from the Cisco Catalyst 6500 Series Supervisor Engine 2T. As a part of this feature, OEAP 600 APs ensure not to reset their CAPWAP tunnel.
